In the current sample, use of coarse Likert response scales to capture relatively fine latent responses caused a substantial reduction in average moderated regression effect size. These results may explain many of the mixed findings in the search for moderator effects over the last 30 years.

However, many authors have expressed concern over the general lack of empirical support for interaction effects reported in the literature. We demonstrate in the current sample that use of a continuous, dependent-response scale instead of a discrete, Likert-type scale, causes moderated regression analysis effect sizes to increase an average of 93%.

Here's my reply. In the question, the researcher asked about logistic regression, but the same answer applies to all regression models. 1. There is a difference between a likert scale item (a single 1-7 scale, eg.) and a full likert scale , which is composed of multiple items.
