In geophysics, vertical seismic profile (VSP) is a technique of seismic measurements used for correlation with surface seismic data. The defining characteristic of a VSP (of which there are many types) is that either the energy source, or the detectors (or sometimes both) are in a borehole. In the most common type of VSP, Hydrophones, or more often geophones or accelerometers, in the borehole record reflected seismic energy originating from a seismic source at the surface.

Dr. Bob Hardage, one of our colleagues, recently shared a remarkable story that highlights the history of Vertical Seismic Profiling (VSP). Bob has been both a researcher and proponent of the technique since its inception in the mid-50's.

Vertical seismic profiling. In VSP, a seismic sensor is lowered to a sequence of selected depths in a well by wireline. Fig. 1 shows the source-receiver geometry involved in VSP. A wall-locked seismic sensor is manipulated downhole by wireline so that the receiver occupies a succession of closely spaced vertical stations.

Acquisition procedure. Make sure tool depth=0 at the well head; Slack the cable after anchoring; Record 5-6 levels as the tool is being lowered; Determine the gain and number of records to stack for required Signal/Noise; Take at least 5 records and monitor quality at every level; Reoccupy the down levels and check the depth and waveforms; Avoid washed out zones;

Vertical seismic profiles A vertical seismic profile (VSP) is recorded in essentially the same way as a checkshot survey. The major difference between a VSP and a checkshot survey is that VSP data are recorded at much smaller spatial sampling intervals than checkshots. While a receiver may be moved a vertical distance of 200
